

# Convertible Vehicle

## Abstract

A convertible vehicle has a rear area with a storage compartment for stowing the top located adjacent to the trunk. A variable partitioning device separates the trunk and the storage compartment. The partitioning device has a top receiving position and a luggage receiving position. The partitioning device has a panel-shaped end member that, in the top receiving position, is in an upright position and delimits rearwardly the storage compartment relative to the trunk. An adjoining panel is connected to the end member. The end member is releasably secured to the carbody. For moving the partitioning device into the luggage receiving position, the end member is detached from the carbody and pivoted relative to the adjoining panel by a forwardly oriented movement. Subsequently, the end member and the adjoining panel are moved together by a second forwardly oriented movement.
